NASM Essentials of Corrective Exercise Training

National Academy of Sports Medicine

Inhibitory techniques: corrective exercise techniques used to release tension or decrease activity of overactive neuromyofascial tissues in the body.

Lengthening technique: corrective exercise techniques used to increase the extensibility, length, and range of motion (ROM) of neuromyofascial tissues in the body.

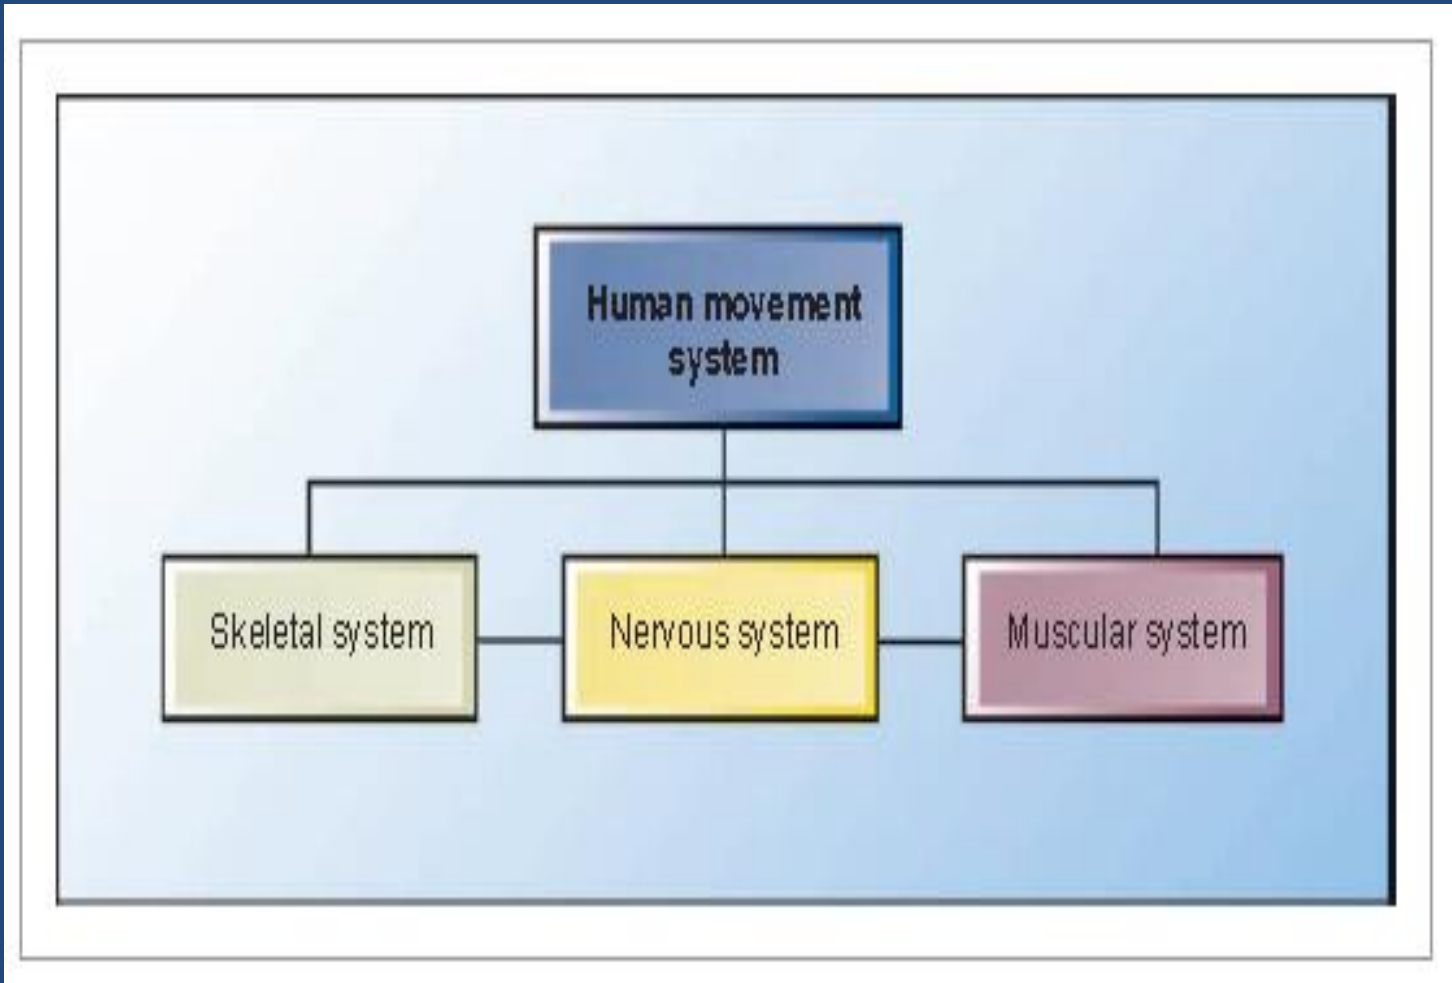

Activation techniques: corrective exercise techniques used to reeducate or increase activation of underactive tissues.

Integration techniques: corrective exercise techniques used to retrain the collective synergistic function of all muscles through functionally progressive movements.

Collectively, the three-step process is to:

1. Identify the problem (integrated assessment)
2. Solve the problem (corrective program design)
3. Implement the solution (exercise technique)

Before implementing the Corrective Exercise Continuum, an integrated assessment process must be done to determine dysfunction and ultimately the design of the corrective exercise program. This assessment process should include (but not be limited to) movement assessments, range of motion assessments, and muscle strength assessments. This integrated assessment process will help in determining which tissues need to be inhibited and lengthened and which tissues need to be activated and strengthening through the use of the Corrective Exercise Continuum. These assessments will be covered in greater detail in the Assessment section of this textbook.

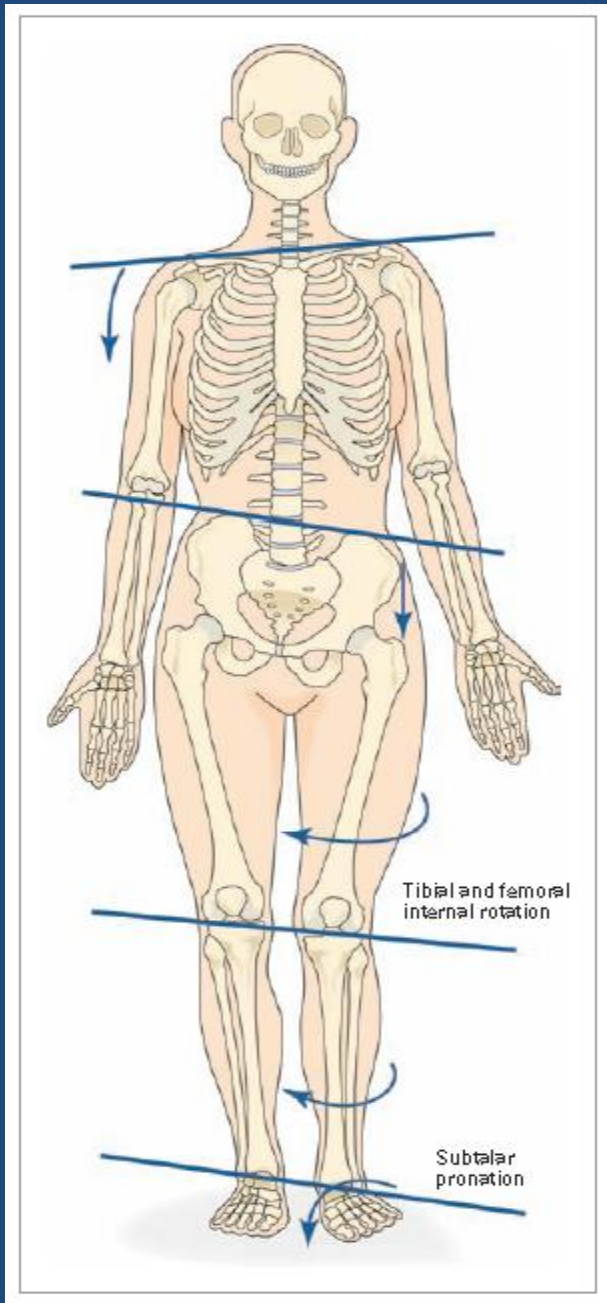

Table 2.3 MUSCLE ACTION SPECTRUM

Concentric	Developing tension while a muscle is shortening; when developed tension overcomes resistive force
Eccentric	Developing tension while a muscle is lengthening; when resistive force overcomes developed tension
Isometric	When the contractile force is equal to the resistive force

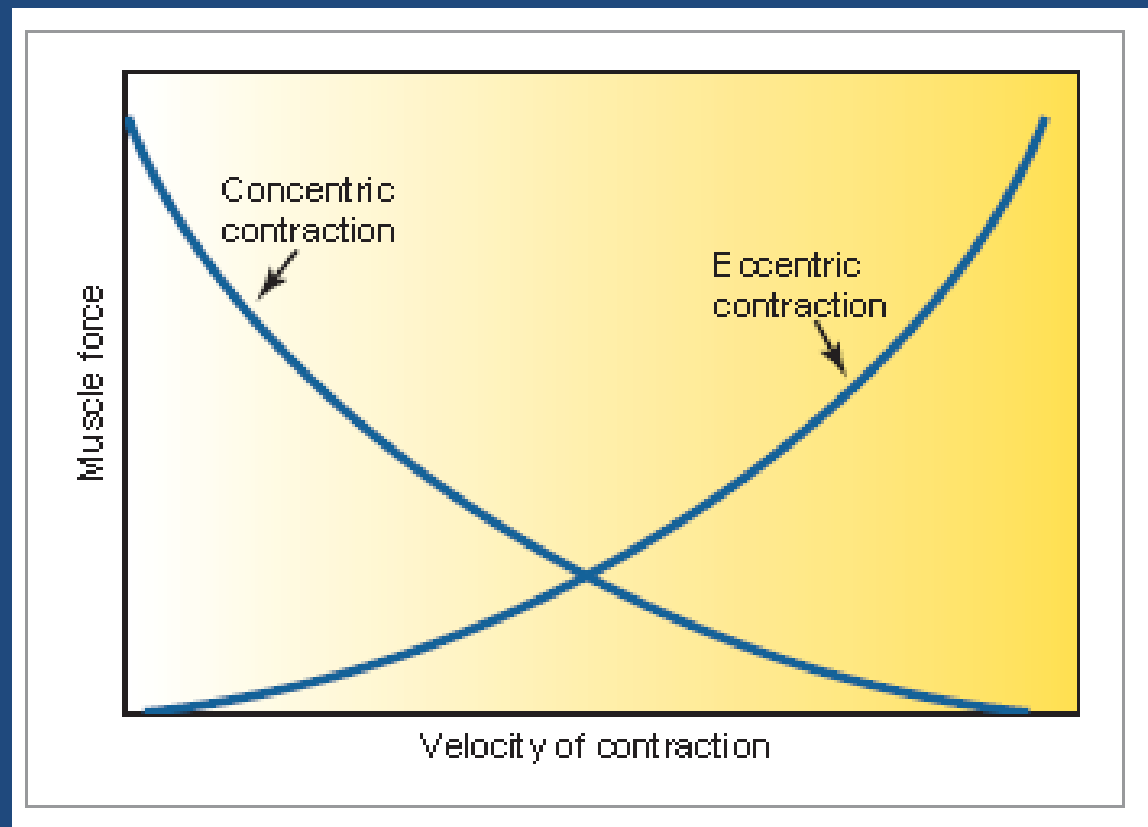

LENGTH-TENSION RELATIONSHIPS

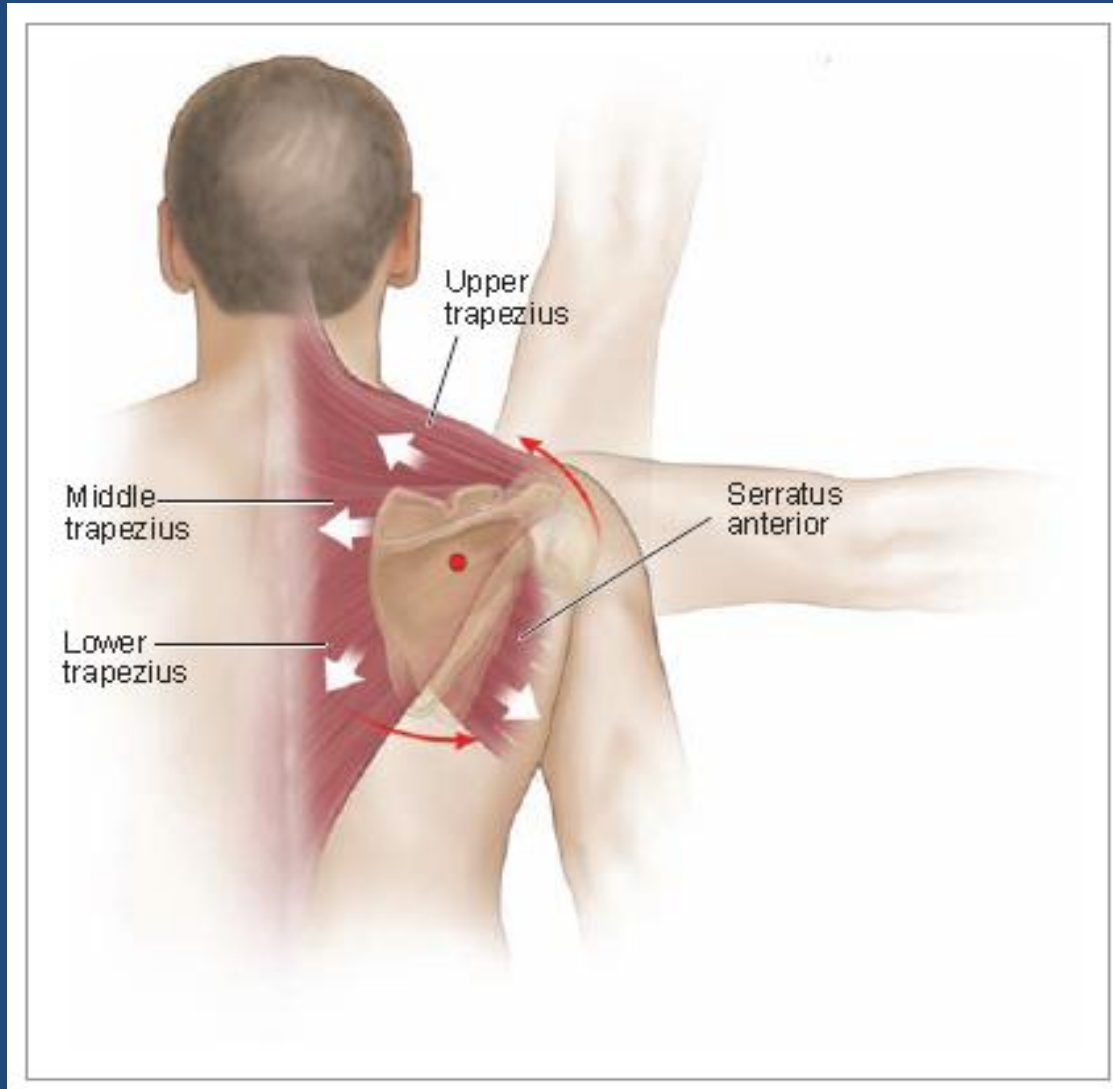

Length-tension relationship: the resting length of a muscle and the tension the muscle can produce at this resting length.

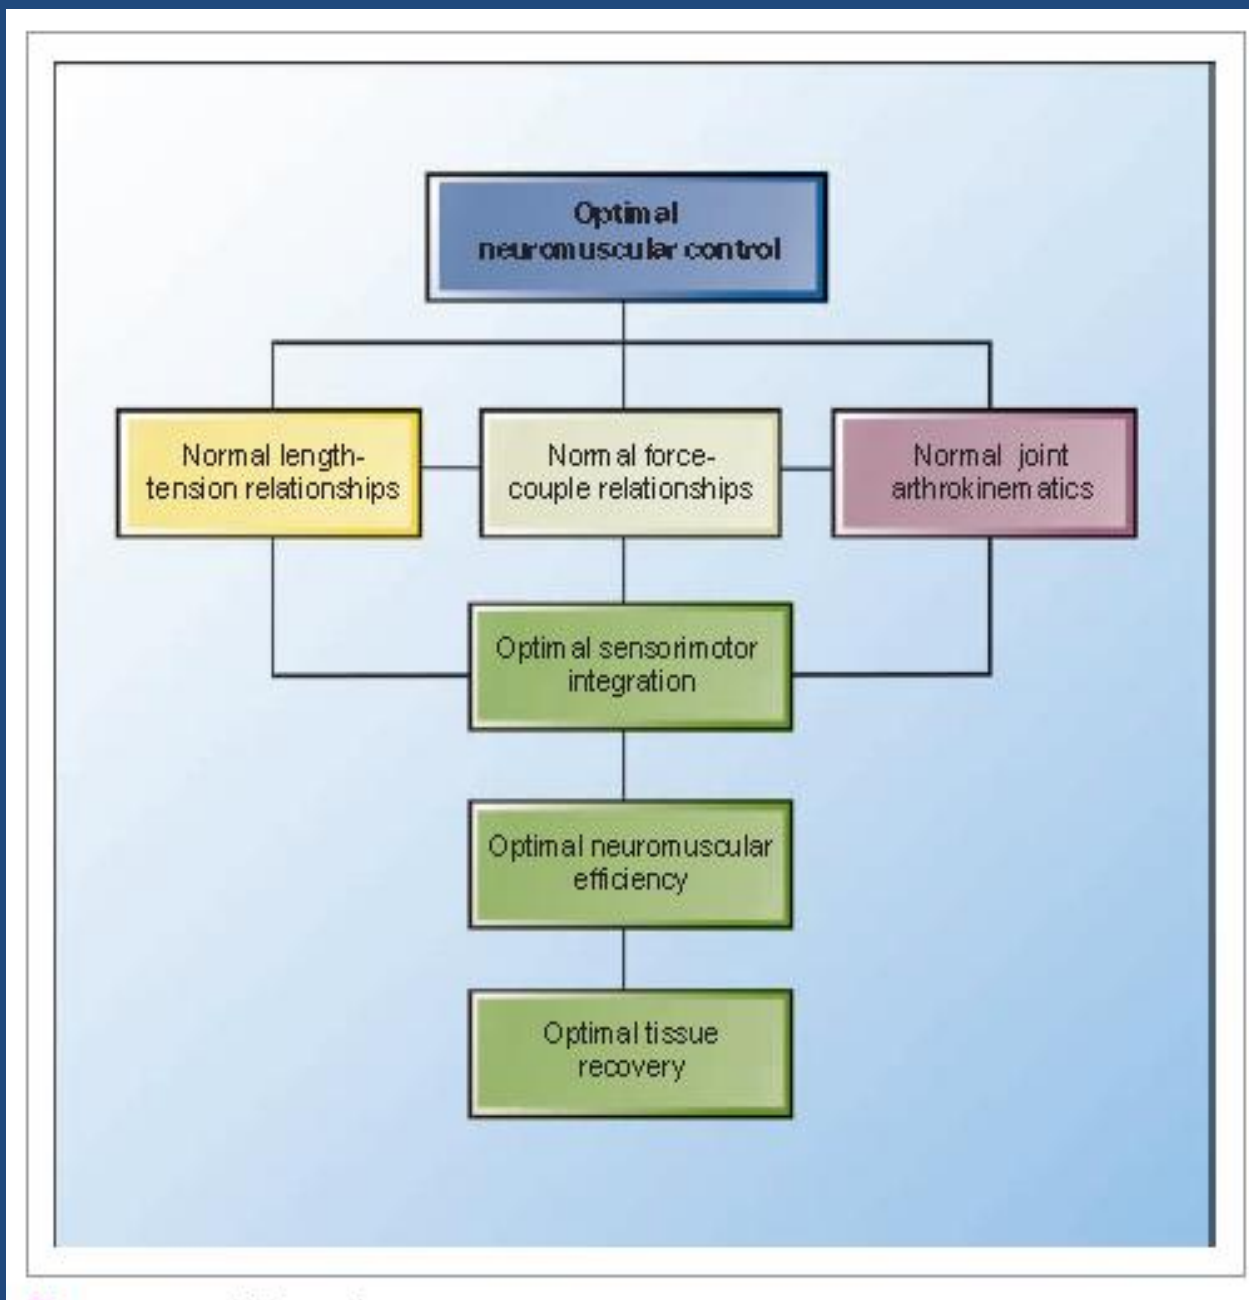

FORCE-VELOCITY CURVE AND FORCE-COUPLE RELATIONSHIPS

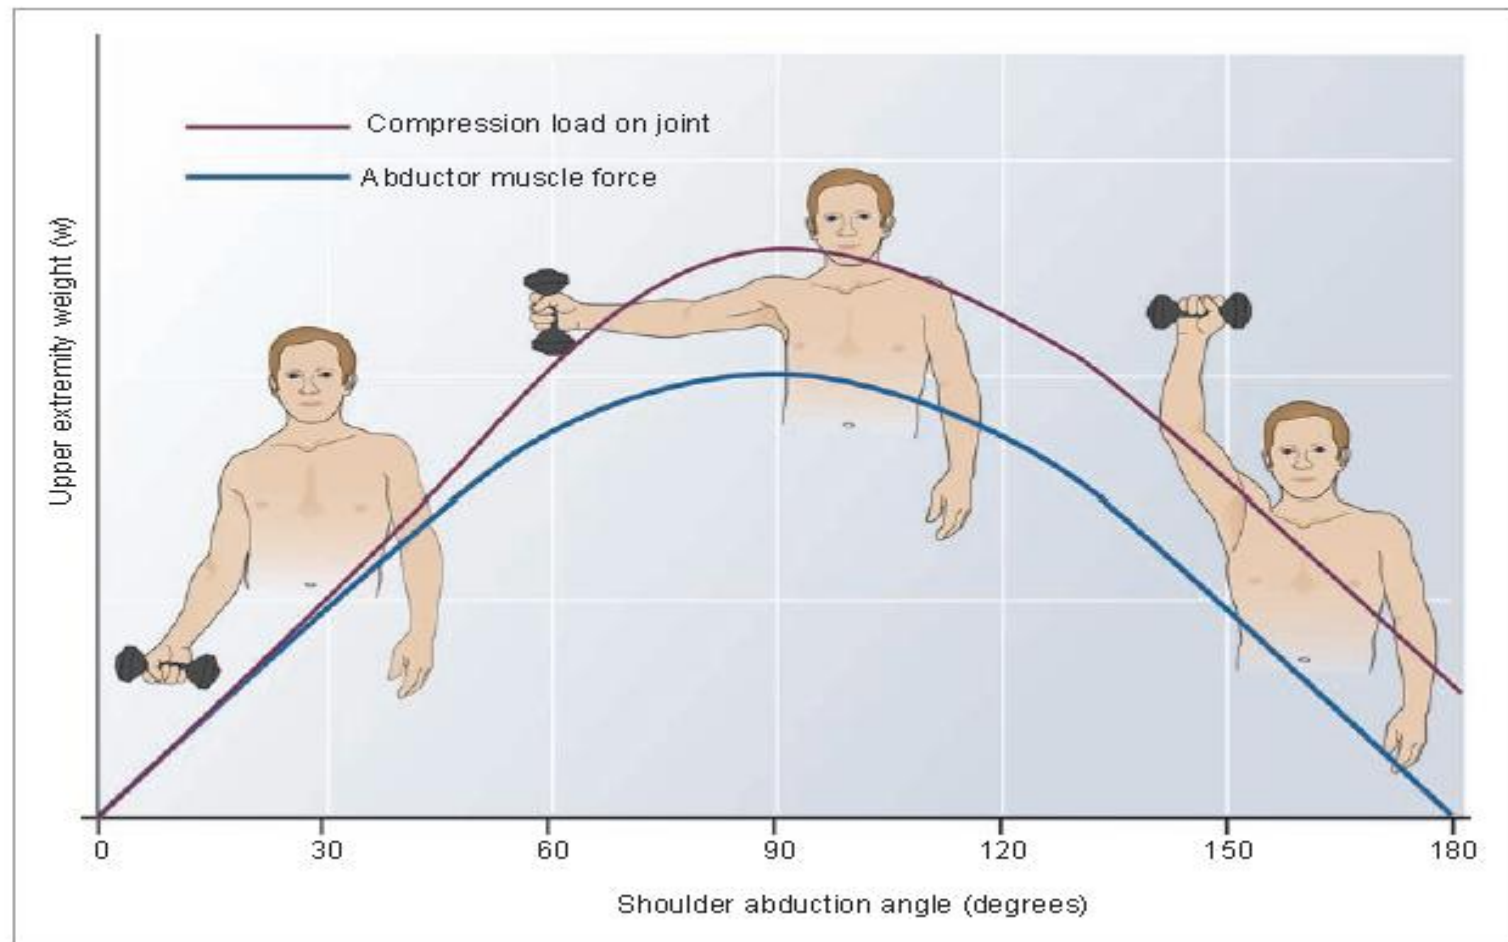

Force-velocity curve: the relationship of a muscle's ability to produce tension at differing shortening velocities.

Load and torque relationship.

FUNCTIONAL ANATOMY

Agonists: muscles that act as prime movers.

Antagonists: muscles that act in direct opposition to prime movers.

Synergists: muscles that assist prime movers during functional movement patterns.

Stabilizers: muscles that support or stabilize the body while the prime movers and the synergists perform the movement patterns.

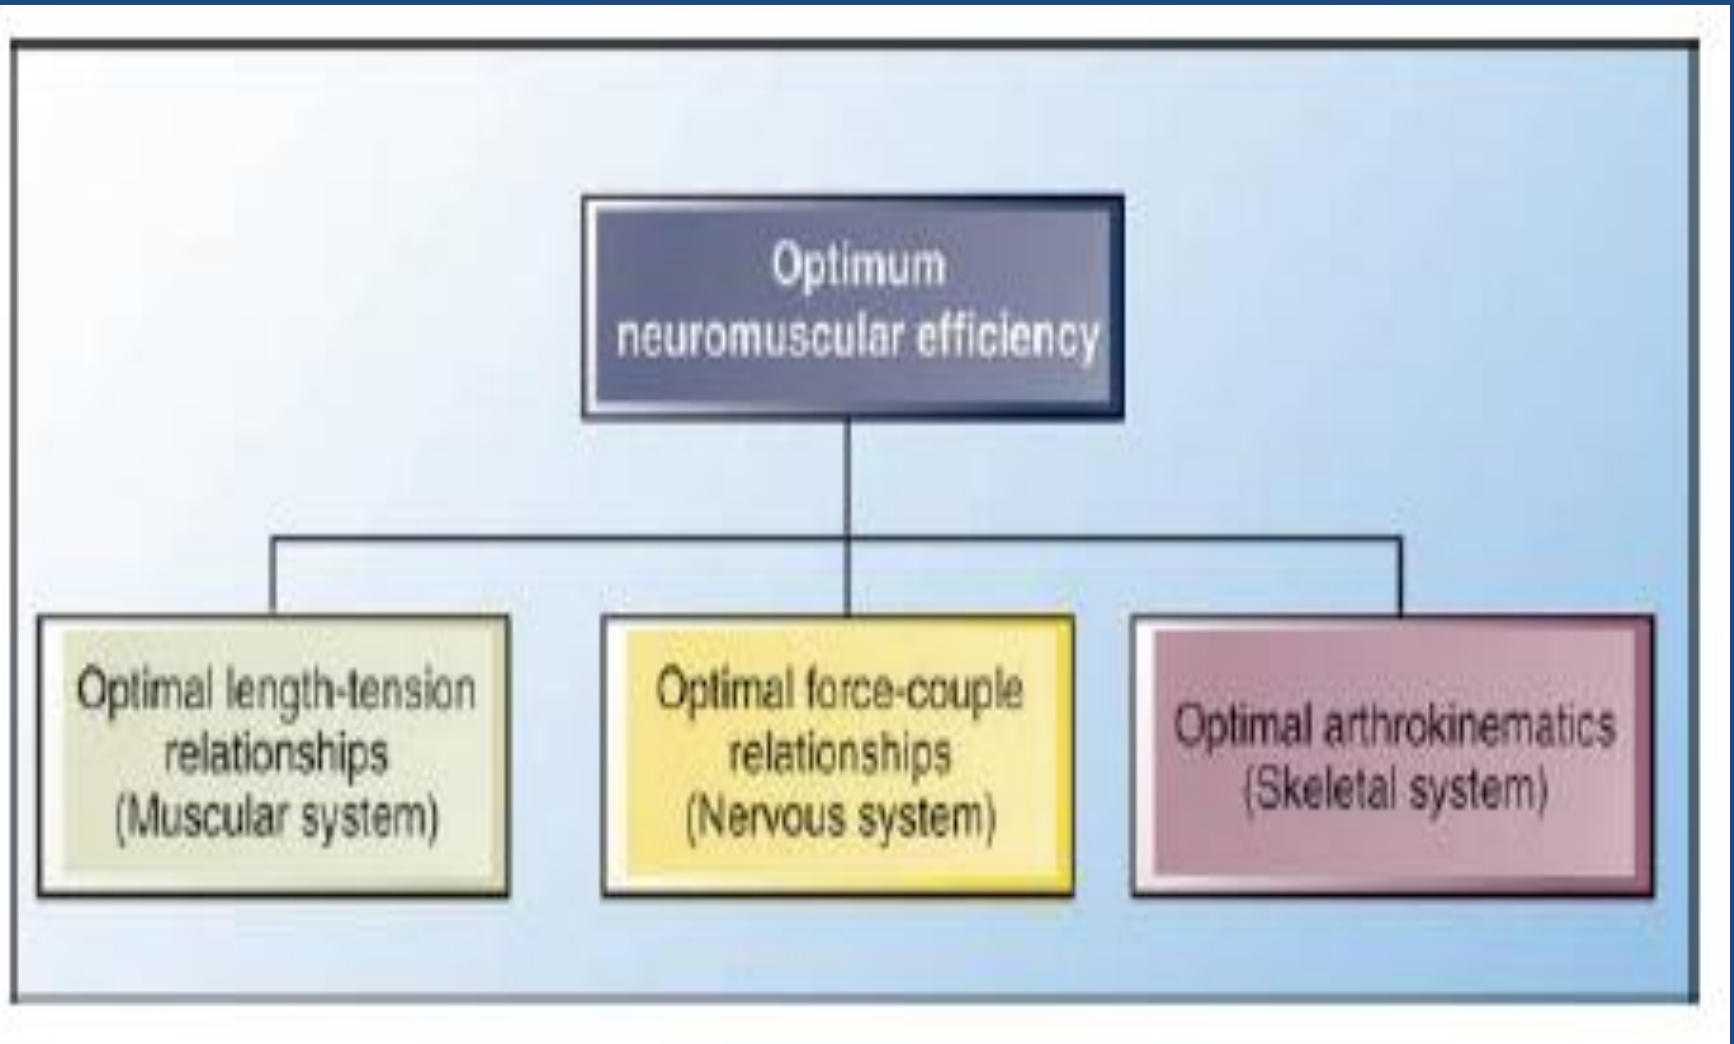

The Local Muscular System (Stabilization System)

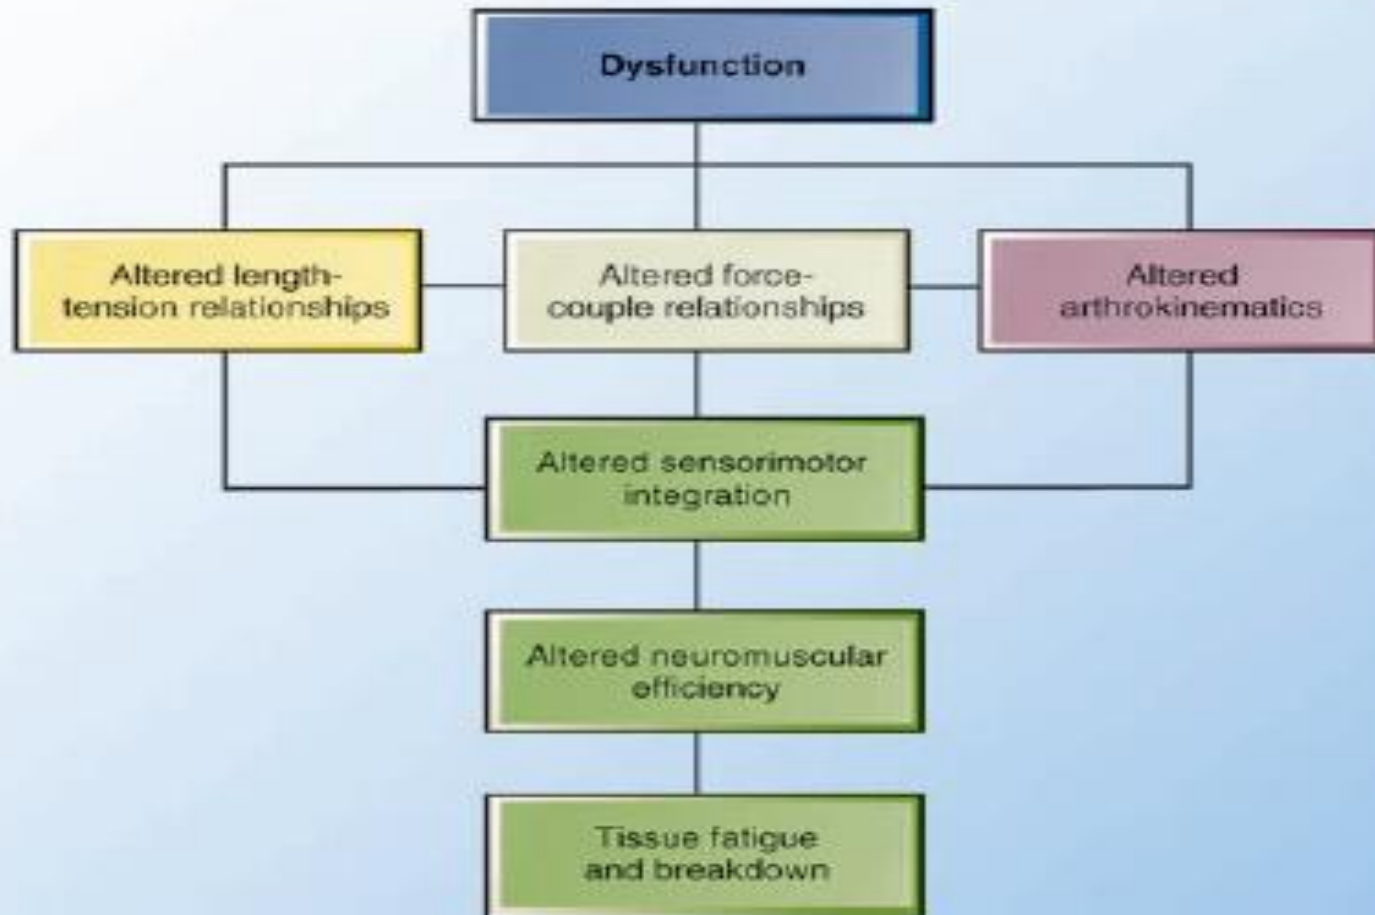

THE GLOBAL MUSCULAR SYSTEMS (MOVEMENT SYSTEMS)

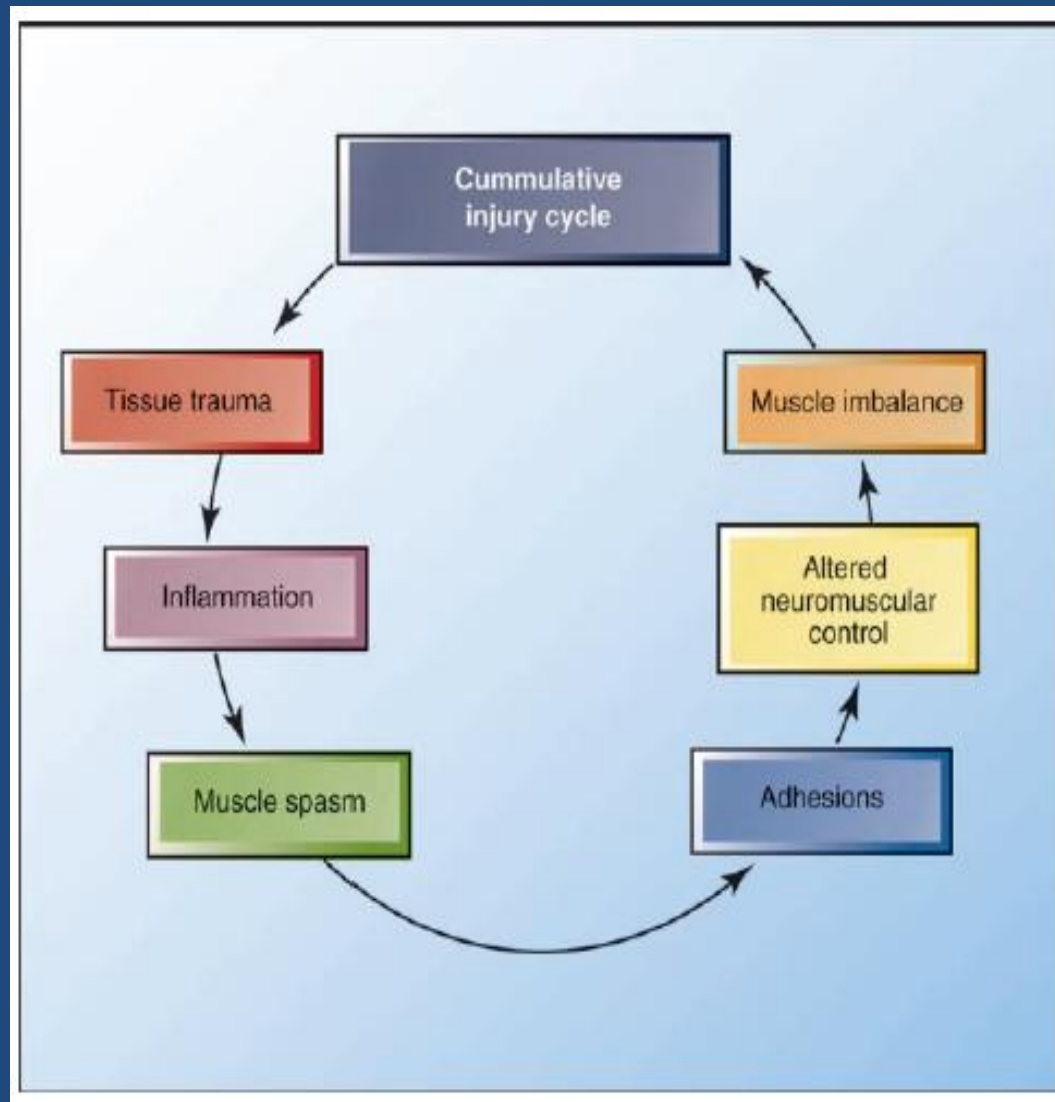

Optimal neuromuscular efficiency.

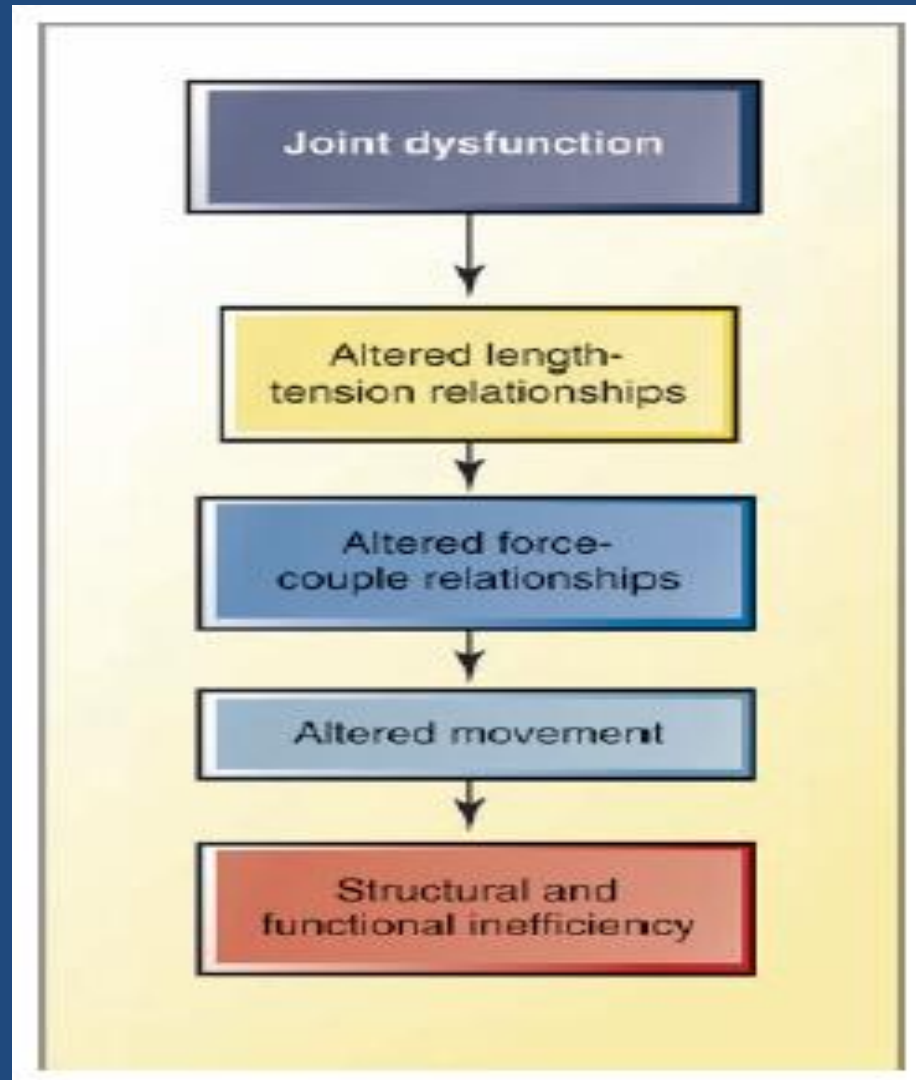

HUMAN MOVEMENT SYSTEM IMPAIRMENT

Cumulative injury cycle.

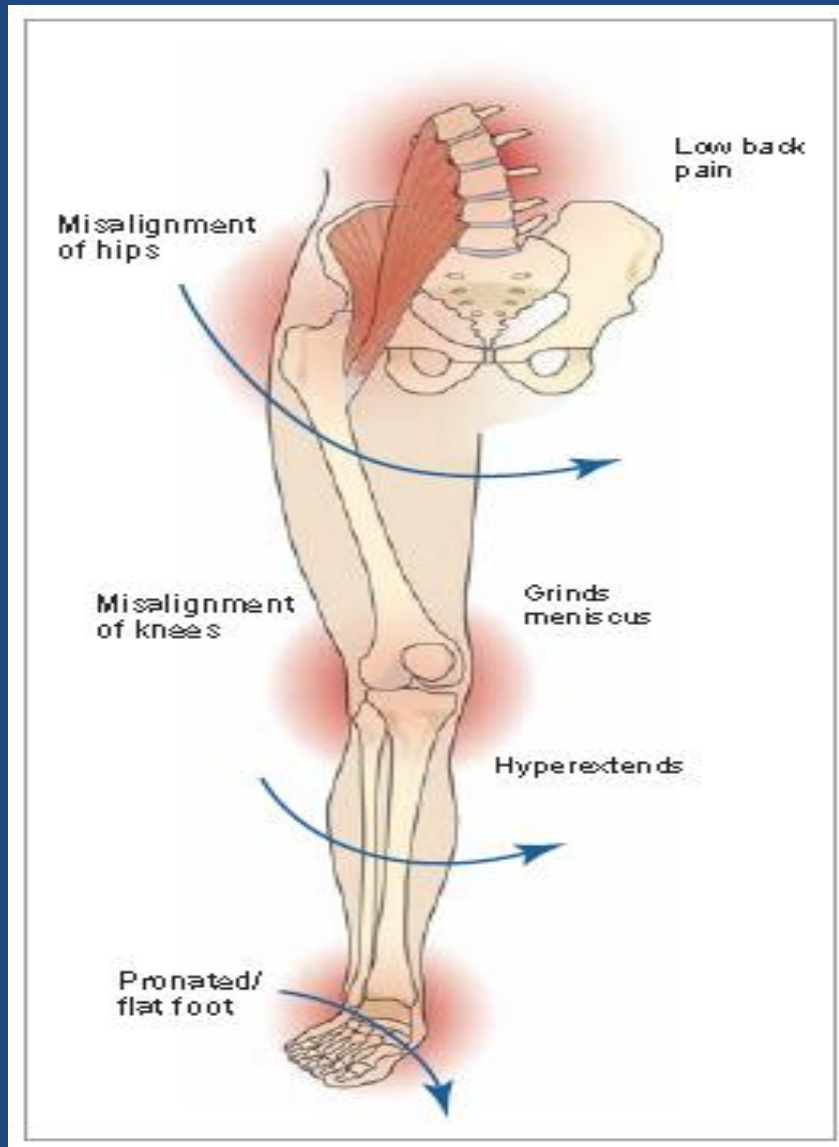

STATIC MALALIGNMENTS

ALTERED MUSCLE RECRUITMENT

DYNAMIC MALALIGNMENTS

Self-Myofascial Release

Lengthening Techniques

Activation Techniques

Integration Techniques
